

PayZo is a Tunisian digital-banking platform that unifies multi-bank account management and protects peer-to-peer transfers through a three-layer machine-learning fraud detection system. The primary scorer is a calibrated LightGBM model (PR-AUC 0.90, ROC-AUC 0.99); a Random Forest backup and a rule-based firewall ensure the platform always produces a risk decision. High-risk transfers are suspended and routed to an analyst review queue—a human makes the final call on every fraud alert.
